Machine Learning – Day to Day

Recommendation systems – Collaborative filtering

Machine Learning – Day to Day

Machine Learning – Definition

Arthur Samuel (1959):

Machine Learning is a Science of getting the computers to “learn”, without being explicitly programmed!

Machine Learning – Definition

Tom Mitchell (1998):

A computer is said to *learn* from experience E with respect to some task T and some performance measure P , if its performance on T , as measured by P , improves with experience E .

Conclusions
○○○○○

Categorization – Approaches to LETOR

- Pointwise
 - Existing ML methods
 - Exact relevance degree of each document
 - Transforming ranking to regression, classification, or ordinal regression
 - SVM-based method, in case of ranking it is binary classification (relevant or irrelevant)
 - input: single document
 - output: ground truth labels ($y = fx$, relevance score)

Categorization – Approaches to LETOR

- Pairwise

- Pairwise classification
- Order correctly pairs of documents
- Closer to ranking than pointwise
- Classification on document pairs
- Minimize the number of miss-classified document pairs.
- input: pair of documents
- output: binary labels $y \in -1, +1$ which indicate if the documents are in correct order
- complexity: quadratic number of documents

Categorization – Approaches to LETOR

- Listwise
 - Entire set of documents associated with query
 - Straightforwardly represents learning to rank problem
 - input: n-dimensional feature vectors of all m candidate docs for given query
 - output: scores of all candidate docs (permutation of feature vectors)
 $sort f x_i_{i=1}^n$

For any *supervised* learning system to perform well, it must often be trained on hundreds (even thousands) of labeled instances.

Sometimes *part of* these labels comes at a little or no-cost:

- Spam flag on email
- Ratings

Learning
○○○○

Ranking
○○○

Learning to Rank
○○○○○○○

Active Learning to Rank
○●○○○

Online Learning to Rank
○○○○○○○

Conclusions
○○○○○

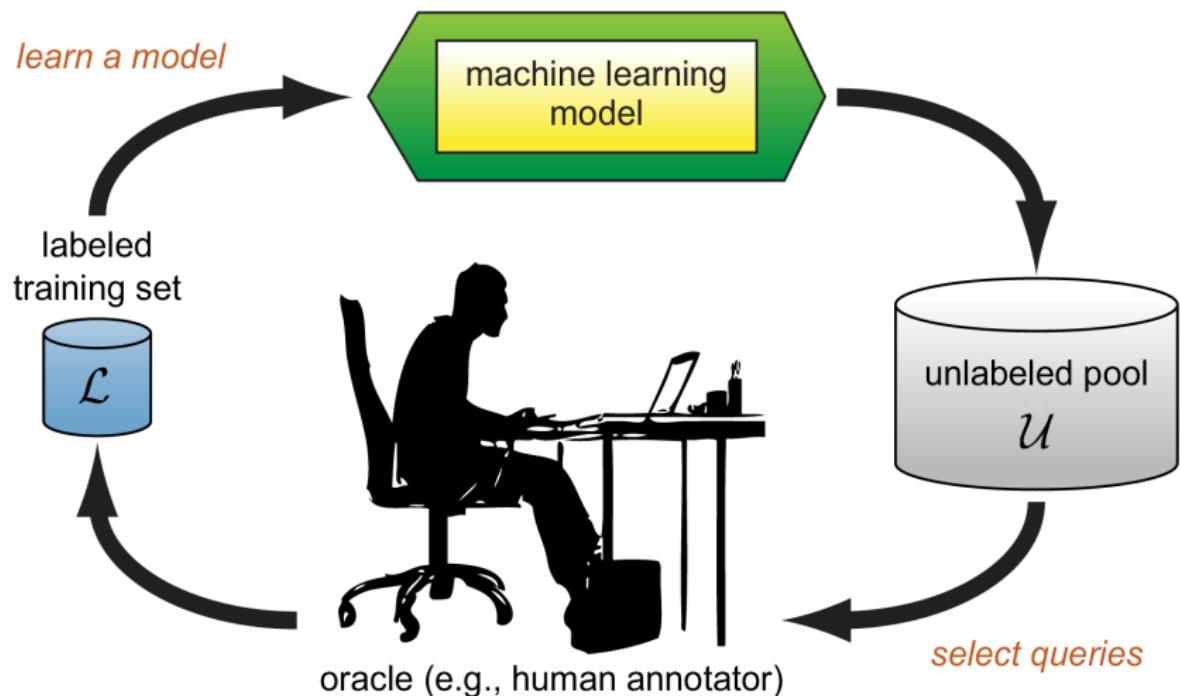

Active Learning to Rank

Active learning to rank systems attempt to overcome the labelling bottleneck.

The learning algorithm is allowed to choose the data from which it learns.

It will perform *better* with less training.

Active Learning to Rank

Co-active Learning to Rank

Co-active learning where both the system and user actively explore possible solution to speedup learning.

Interactions are modeled such that the system presents an initial ranked list, which is then improved by the user.

It was shown that feedback provided in this way can lead to effective learning.

Problems with Active Learning

The focus of active learning is to reduce manual labelling effort. However:

- They are not designed to learn from natural user interactions, happening live!.
- Because they are offline!
- There is a need for online learning!

Problems with Active Learning

Quality of user feedback

How to interpret users interactions and hence behaviour for LETOR?

- Explicit relevance feedback
 - Users indicate if the items are relevant or not-relevant
 - Expensive
 - Requires users time and efforts
- Implicit relevance feedback
 - Log user interaction information and use it to infer users' satisfaction
 - All aspects of users interactions, click, mouse movements, dwell time, gaze, already installed items, you name it!
 - Much cheaper, in comparison to explicit feedback, by product of user interaction
 - But typically much noisier than explicit
 - Therefore interpretation and use is much more difficult

Lets take an example of the implicit feedback.

- How to make sense out of it?
- How to accurately interpret it?
- Higher ranked results usually get more clicks, independent of how relevant they are!

Click through data – highly valuable source of relevance information

Largely used implicit feedback, in most of the learning to rank for recommendation and IR.

To some extent depict users behaviour.

Can be collected in large quantity at reasonably low cost. But:

- How to make sense out of it?
- How to accurately interpret it?
- Higher ranked results usually get more clicks, independent of how relevant they are!
- It is too noisy

Click through data – highly valuable source of relevance information

Largely used implicit feedback, in most of the learning to rank for recommendation and IR.

To some extent depict users behaviour.

Can be collected in large quantity at reasonably low cost. But:

- How to make sense out of it?
- How to accurately interpret it?
- Higher ranked results usually get more clicks, independent of how relevant they are!
- It is too noisy
- But still found to be useful in both research and practice.

Click through data – highly valuable source of relevance information

Clicks to be used **NOT** as an absolute feedback but relative to its context (whether a clicked item is more or less relevant to the non-clicked item in the proximity)

Classical click models

- Position model
- Cascade model

Classical click models

- **Position model** – click depends on both relevance and examination.
 - Each document has certain probability of being clicked (examined).
 - Which decays by, and only depends on rank positions.
 - A click on document indicate the document is examined and relevant.
 - *In the hind side, this model treats documents individually*

Classical click models

- **Position model** – click depends on both relevance and examination.
 - Each document has certain probability of being clicked (examined).
 - Which decays by, and only depends on rank positions.
 - A click on document indicate the document is examined and relevant.
 - *In the hind side, this model treats documents individually*
- **Cascade model** – user examine results sequentially and stop as soon as relevant doc is clicked.
 - The probability of examination is indirectly determined by two factors:
 - 1 Rank of the doc
 - 2 Relevance of all previous docs
 - *It makes strong assumption that only one doc is clicked per search and hence does not explain abandoned search and multiple clicks.*

Classical click models

There is difference between the *perceived* relevance and *actual* relevance.

There are other models as well which solves the above mentioned issues, **but out of scope of this presentation.**

6 Conclusions

Conclusions

- Huge theoretical and practical potential.
- Large amount of existing work and focus from both IR and AI communities.
- Over 100 publications in the top IR venues SIGIR, CIKM, KDD and others.
- Benchmark datasets – publicly available from Yahoo! (Verizon media ☺) and Microsoft (from Learning to Rank challenge).
- Wide range of application scenarios.
- High prospects in near and possibly far future.
